Game Systems Design – GAME-10017-02

Assignment #1 – Tetris Puzzle

Characteristics of the Heptomino Piece

In my design, I used an F-shaped heptomino piece consisting of 7 squares. Because the piece has an asymmetrical structure, it occupies a significant amount of space. Therefore, the F-shaped piece I designed does not easily and perfectly fit on flat surfaces; it requires specially designated spaces

on the board. Due to its large size, this piece distinguishes itself from standard Tetris pieces and makes the player's placement decisions more challenging and meaningful.

The Relationship Between Piece Sequence and the Board

The piece sequence is designed to have a significant impact on the board. The first pieces to arrive clear a row and must perfectly fill the space where the F-shaped piece will appear, gradually filling that space.

The player may not initially realize the consequences of these placements, but when piece F arrives, it aligns with the previously created gap and can simultaneously clear rows 1-3. This design perfectly constitutes the Big Bang point.

The Challenge Presented to the Player

The board and piece design forces the player to focus more on reading the space and thinking, rather than speed. The player's task is to interpret the gaps not as errors, but as clues for future pieces. Since at least one row must be cleared each time a piece is placed, the player has limited opportunities to try. This makes careful planning and understanding the relationships between the pieces crucial.

In conclusion, this design uses the F piece, piece sequence, and board position to create a completely system-based puzzle experience without altering the classic Tetris rules. The design

aims to demonstrate how the connections between features, behaviors, and relationships affect the player experience.
